The world of secure communications

Security on application level

Secure, rule-based remote access to company applications and documents for employees and partners.

- » Central access point for all relevant applications
- » Wide range of possible authentication mechanisms (Microsoft Active Directory, Radius, Lotus Directory) which can be expanded using additional products such as PointSharp ID
- » Transparent single sign-on
- » One-time password via SMS (Pointsharp ID) – no separate tokens necessary

Free assignment of privileges according to the following criteria:

- » Per application / resource
- » Per user / user group (using the data from the Active Directory)
- » Depending on type of connection and place of use
- » Depending on end device and status (how up-to-date the AV is etc.)
- » Device endpoint security via client checking regardless of the operating system used

Central, adaptable, personalized start portal for users

Perimeter security

- » Edge firewall, stateful packet inspection
- » Forward and reverse proxy with optional caching
- » NEW: certified according to Common Criteria EAL4+
- » Highly scalable thanks to clusterability

Branch networking

Simple connection of branch offices using state-of-the-art VPN technologies such as IPSec or L2TP. Central management of the rules of the branches (firewall, content, etc.)

Microsoft®
Exchange Server 2007

Microsoft®
Office Outlook Webaccess
Microsoft®
Office SharePoint Server 2007

Content Security

Protection of company content on gateway level via URL filters, virus filters, spam filters and much more.

- » Easy, automated installation of software packages from third-party manufacturers via the SecureGUARD web interface.
- » With IKARUS products, the URL filter configuration is integrated into ISA administration, thus making the latter much easier to do.

Cloud Computing

The secure use of distributed processes in the case of cloud computing is only possible via flexible, adaptable web application firewalls.

SSL-VPN allows mobile users, home workplaces, branches and connected companies to access the corporate network via web browser technologies regardless of the platform used.

Sometimes only web browsing is possible in external networks, so a conventional VPN connection into the internal company network is not possible. This problem is solved by the SSL-VPN technology provided by IAG 2007.

Integration into the Microsoft infrastructure

Reduced administrative effort is guaranteed by the use of existing structures such as Active Directory, thus allowing single sign-on etc.

- » The use of the existing Microsoft infrastructure such as Active Directory guarantees efficient interaction
- » Flexible integration into Active Directory via LDAP support
- » Central administration of privileges

Windows Server®
Active Directory

The world is opening up – and security is changing

Companies

„Changing all the time“

Companies are changing and networking more and more. They are in close contact with their service providers and suppliers as well as their worldwide locations via their company network.

Working methods

„Flexibility is becoming more and more important“

The working methods of the employees are changing. The latter are flexible and work in various offices, in home offices and en route. More and more applications are being used as multi-network applications and in group work.

Communication paths

„Shifting to the Internet“

The company networks and the communication paths in the network are changing. The infrastructure is consolidating, and contact to service providers, branches or mobile employees is shifting more and more to the „cloud“ of the Internet.

Unternehmenssicherheit

„At the centre“

These new networks and the changes in user behaviour as well as the development of completely new programs and program types require different and more sophisticated measures for corporate security than before. Just a few years back, there was only one central transition point from the company network to the Internet. Now every company has a variety of ways to access the World Wide Web: at every company location, for every mobile employee and for every supplier. Each part of this cloud of access methods and applications makes its own special demands on the security of the content.

ISA Server 2006, IAG2007

„Security solution“

The secure solution for modern networks in the Microsoft environment is called „Security Gateways from SecureGUARD“ and is equipped with the tried and tested security solutions from Microsoft: ISA Server 2006 and IAG 2007.

SecureGUARD – simple, secure and flexible

VPN, SSL-VPN

„Secure remote access“

SecureGUARD offers companies all basic security functions of the network infrastructure such as VPN, SSL-VPN and Proxy as well as sophisticated content security: applications and contents are checked and can be blocked and logged. In this way, the solutions do justice to the demands which will be made on modern communication infrastructures in the future.

Active Directory

„One-time authentication“

SecureGUARD systems communicate directly with the Microsoft Active Directory and authenticate themselves centrally there – separate user administration is unnecessary. Authorizations can be assigned in an individual and highly granular way.

Outlook Web Access, SharePoint

„Web-based e-mail client and data access“

For the publication of Microsoft applications such as Outlook Web Access and SharePoint, there are pre-prepared profiles allowing the system to be taken into operation rapidly and simply for the purposes of secure access to these applications – regardless of the companies and locations involved.

SecureGUARD web interface

„Remote verification of security solutions“

The current security status of devices can be accessed regardless of the operating system used and access to applications can be restricted in a finely graded way.

SecureGUARD Security Gateways

„A future-proof security solution“

The SecureGUARD Security Gateways equip companies for the future. This is done via a central, multi-function security solution for decentralized communication on the highest possible security level – highly integrated into modern Microsoft environments.
